CPT_S 515 Advanced Algorithms HW#3

1. Step 1: Since the intruder cannot observe A but he can observe B, I define A is private variable and B is public variable. Information leaked from A to B. A and B are from one message, so A and B are dependent. Define in a message string C, there are two variables

$$A = \langle a_1, a_2, \dots, a_k \rangle$$

$$B = \langle b_1, b_2, \dots, b_k \rangle$$

Step 2: Draw a bipartite graph G for C with joint distribution $p(A, B)$.

$$A = \langle a_1, a_2, \dots, a_k \rangle$$

$$B = \langle b_1, b_2, \dots, b_k \rangle$$

Step 3: The k is a function of time t . In this case, the graph G can be expanding over the time. We can approximate the rate of info-leak .

$$\lambda_G = \limsup_{t \rightarrow \infty} \left(\frac{1}{t} \log_2 \frac{N_{Left} \cdot N_{Right}}{E} \right)$$

Step 4: A and B takes 10 bits, for each A, there is one and only one B corresponding to it.

Then we get:

$$\lambda_G = \limsup_{t \rightarrow \infty} \left(\frac{1}{t} \log_2 (100k) \right)$$

Step 5: For the average of bits actually leaked from A to B, we calculate:

$$I(A; B) = 10 * \lambda_G$$

Ideally, the value of $I(A; B)$ should be less than 1 bit.

2. Step 1: Translate each statement into an integer linear constraint. If it is a linear combination of integer variables. For example,

$$x_1 := x_1 + x_2$$

$$\Rightarrow x_1' := x_1 + x_2 \text{ and all other } x_n' \text{ s no change}$$

If it is an if-then-else statement where the condition is a comparison between two linear constraints. I split it into two integer constraints. Then we repeat assigning new value to x_n .

Step 3: Change RHS to nonnegative. Move all elements in the right-hand side to left or multiply negative 1 to both sides.

Step 4: Combine all statements in program into a big ILP instance. For each constraint, we add “artificial variables”, $\alpha_1, \alpha_2, \dots, \alpha_n$ and then we get that ILP instance. We want the value of $\min x$.

Step 5: Observe that:

If the minimum of the $x < 0$, then the program returns negative integer.

Otherwise, the program dose not return negative integer.

3. Step 1: Since the Bell Number can count the possible partitions of a set, the number of set P's can be calculated by B_k . For example, if $K = \{1,2,3\}$, $k = 3$, $B_3 = 5$.

$$\begin{aligned}
 K &= \langle 1, 2, 3 \rangle & B_3 &= 5 \\
 P_1 &= \{ \{1\}, \{2\}, \{3\} \} & \longrightarrow & C_{P_1} \\
 P_2 &= \{ \{1, 2\}, \{3\} \} & \longrightarrow & C_{P_2} \\
 P_3 &= \{ \{1\}, \{2, 3\} \} & \longrightarrow & C_{P_3} \\
 P_4 &= \{ \{1, 3\}, \{2\} \} & \longrightarrow & C_{P_4} \\
 P_5 &= \{ \{1, 2\}, \{3\} \} & \longrightarrow & C_{P_5}
 \end{aligned}$$

Step 2: We use a binary number n to represent a C_p . Since C is 1-1, we need at least $\lceil \log_2 B_k \rceil$ bits memory to store the total number of C_p .

For instance, if $k = 5$, $B_k = 15$, we need at least $\lceil \log_2 15 \rceil = 4$ bits.

Step 3: All C_p can be represented by a binary number which size is n bits.

4. Number of variables needed to represent 2048 nodes:

$$\begin{aligned}
 2^x &= 2048 = 2^{11} \\
 x &= 11
 \end{aligned}$$

Number of Boolean variables needed is:

$$N = 2 * x = 22$$

5. Consider one binary number can and only can represent one student, we need n bits to store all 40 students, and n should satisfy:

$$2^n \geq 40$$

$$n \geq 6 \text{ (} n \text{ is a positive integer)}$$

So, we need at least 6 bits to store all 40 students.
